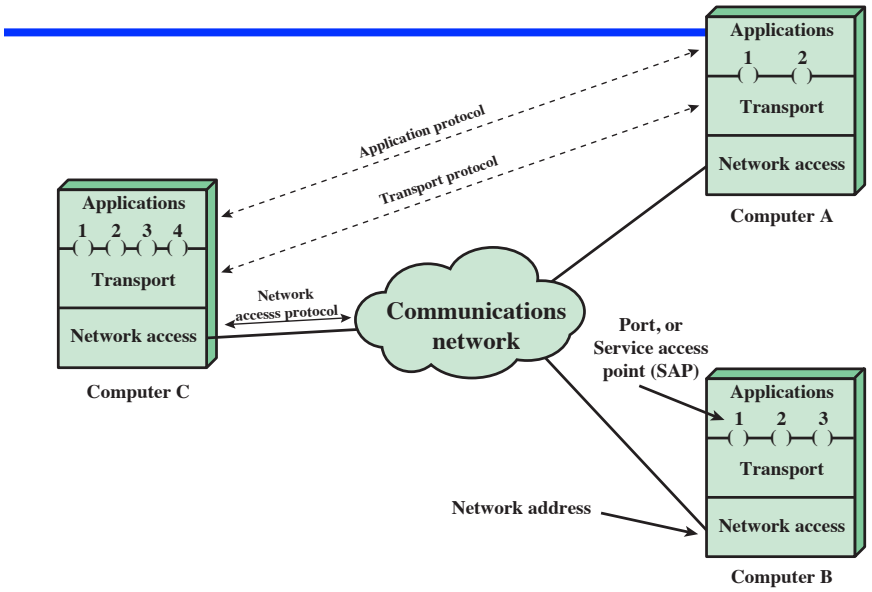
Chapter 2

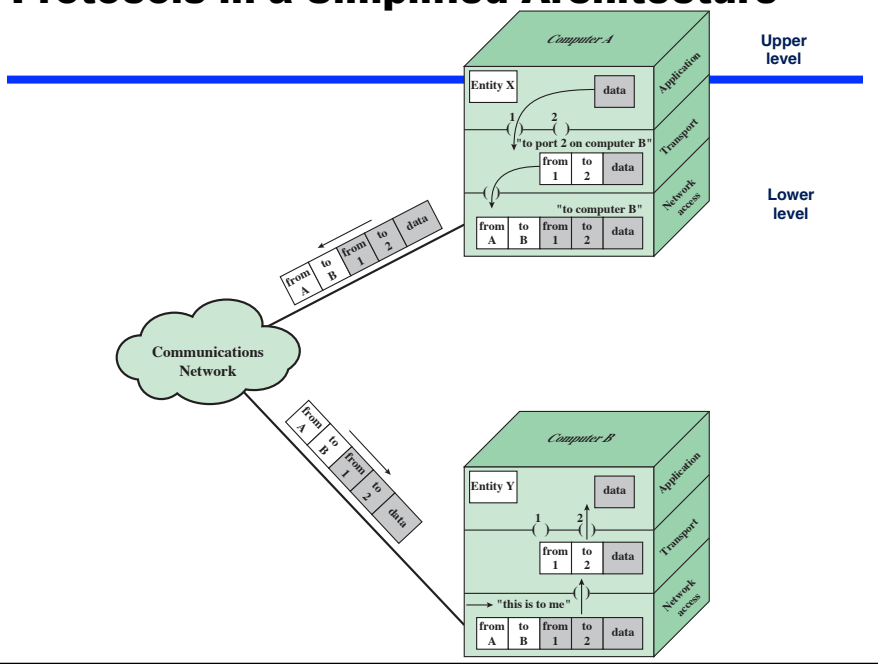
Need For Protocol Architecture

- E.g. File transfer
  - —Source must activate communications path or inform network of destination
  - —Source must check destination is prepared to receive
  - —File transfer application on source must check destination file management system will accept and store file for his user
  - —May need file format translation
- Task broken into subtasks
- Implemented separately in layers in stack
- Functions needed in both systems
- Peer layers communicate

Protocol Architecture and Networks



Protocols in a Simplified Architecture



Key Elements of a Protocol

- Syntax
  - —Data formats
  - —Signal levels
- Semantics
  - —Control information
  - —Error handling
- Timing
  - —Speed matching
  - —Sequencing

Standardized Protocol Architectures

- Required for devices to communicate
- Vendors have more marketable products
- Customers can insist on standards based equipment
- Two standards:
  - —OSI Reference model
    - Never lived up to early promises
  - —TCP/IP protocol suite
    - Most widely used
- Also: IBM Systems Network Architecture (SNA)

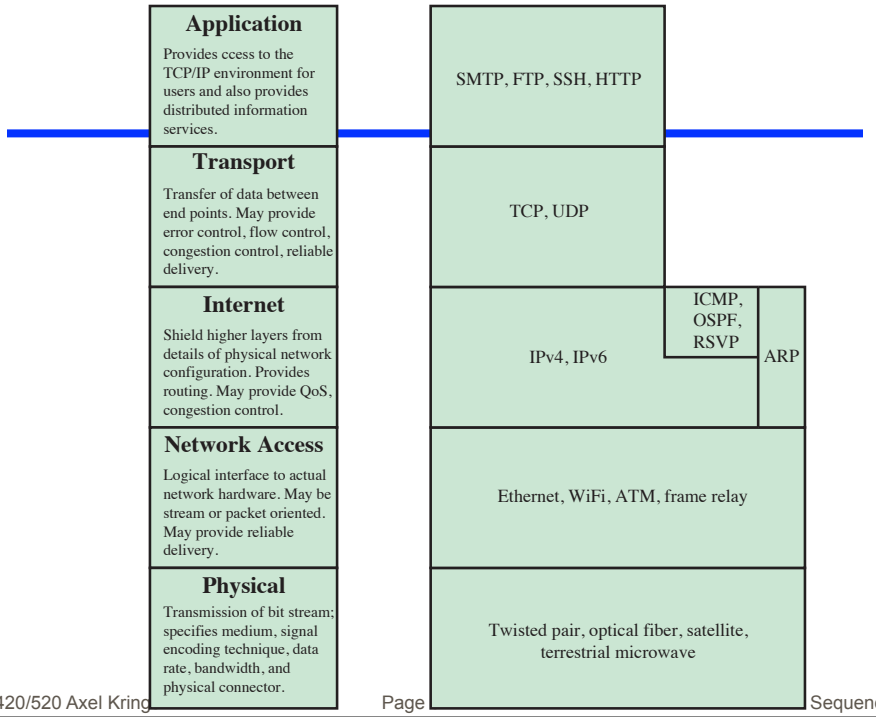
The main Architecture now

TCP/IP Protocol Architecture

- developed by US Defense Advanced Research Project Agency (DARPA)
- for ARPANET packet switched network
- used by the global Internet
- protocol suite comprises a large collection of standardized protocols

TCP/IP Layers

- this is not an official model but a working one
  - —Application layer
  - —Host-to-host, or transport layer
  - —Internet layer
  - —Network access layer Connect nodes
  - —Physical layer



Physical Layer

- concerned with physical interface between computer and network
- concerned with issues like:
  - —characteristics of transmission medium
  - —signal levels
  - —data rates
  - —other related matters

Network Access Layer

- exchange of data between an end system and attached network
- concerned with issues like :
  - —destination address provision
  - —invoking specific services like priority
  - —access to & routing data across a network link between two attached systems
- allows layers above to ignore link specifics

Internet Layer

- routing functions across multiple networks
- for systems attached to different networks
- using IP protocol
- implemented in end systems and routers
- routers connect two networks and relays data between them

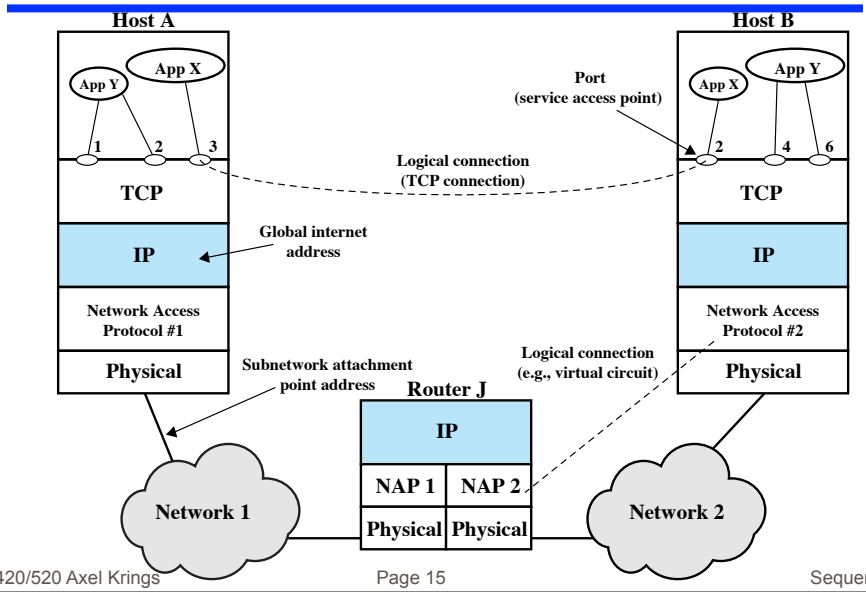
Transport Layer

- common layer shared by all applications
- provides reliable delivery of data
- in same order as sent
- commonly uses TCP

Application Layer

- provide support for user applications, e.g., ftp, email
- need a separate module for each type of application

Operation of TCP and IP



FTP has 2 ports: 20 and 21

Addressing Requirements

- two levels of addressing required
- each host on a subnet needs a unique global network address
  - —its IP address

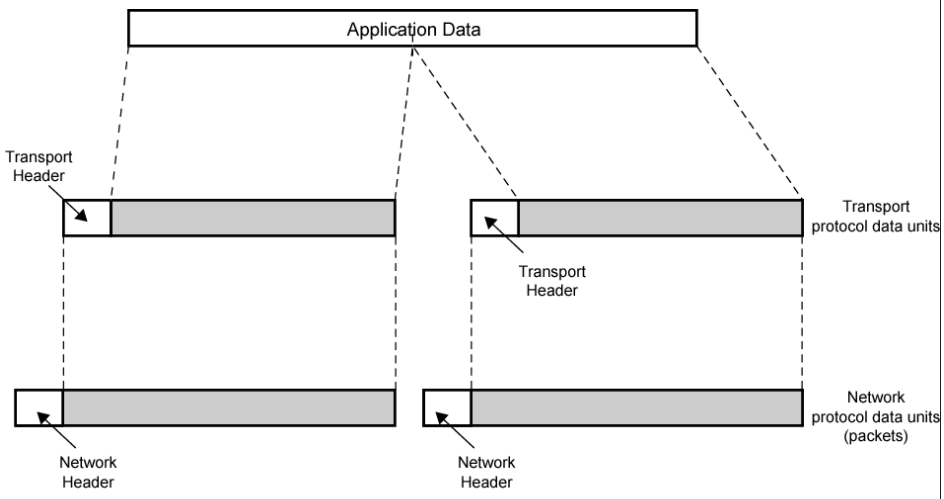
IPv4 - 32
IPv6 - 128

- each application on a (multi-tasking) host needs a unique address within the host
  - —known as a port

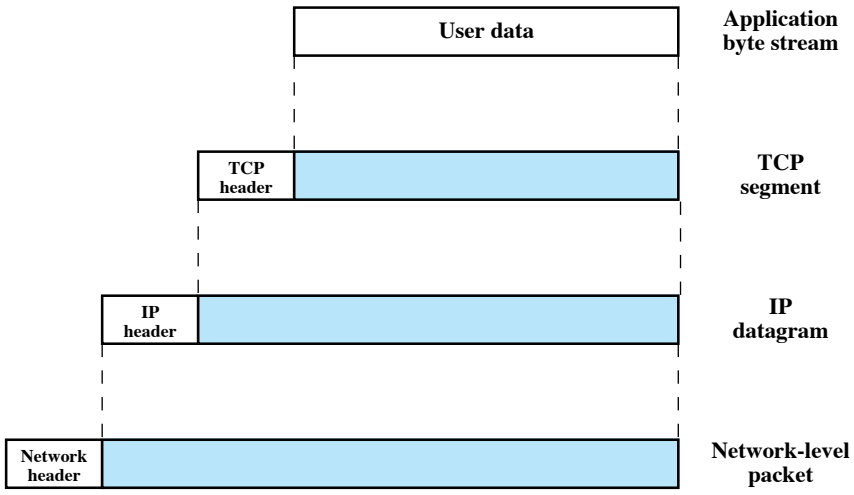
Protocol Data Units (PDU)

- At each layer
  - — protocols are used to communicate
  - — control information is added to user data
- Transport layer may fragment user data
  - —Each fragment has a transport header added
    - Destination SAP (service access point)
    - Sequence number
    - Error detection code
  - —This gives a transport protocol data unit

Protocol Data Units



Operation of TCP/IP

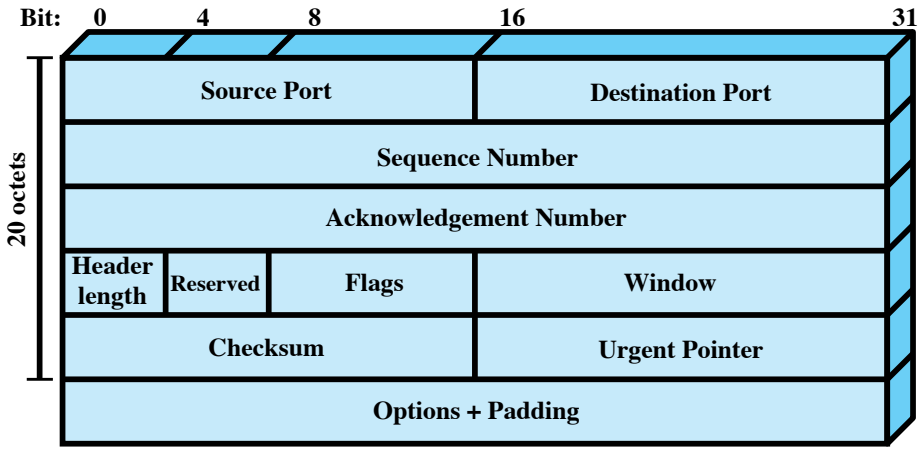


TCP

Assignment: Read and understand here

- Usual transport layer is **T**ransmission **C**ontrol **P**rotocol
  - Reliable connection
  - RFC 793 from 1981
- Connection
  - Temporary logical association between entities in different systems
- TCP PDU
  - Called TCP segment
  - Includes source and destination port (c.f. SAP)
    - Identify respective users (applications)
    - Connection refers to pair of ports
- TCP tracks segments between entities on each connection

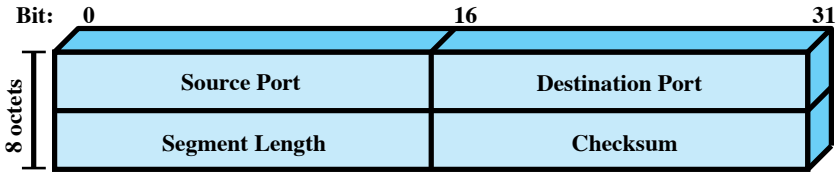
TCP Header



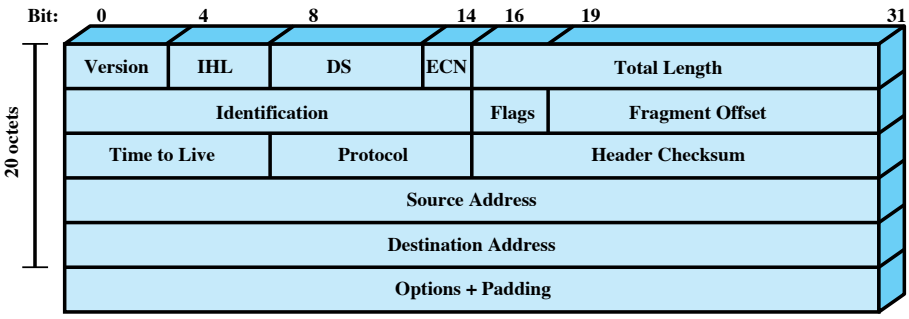
User Datagram Protocol (UDP)

- an alternative to TCP
- no guaranteed delivery (...it is a datagram)
- no preservation of sequence
- no protection against duplication
- minimum overhead
- adds port addressing to IP

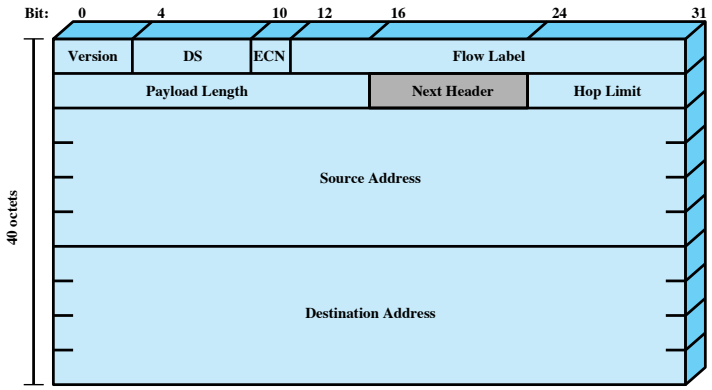
UDP Header



IP Header



IPv6 Header



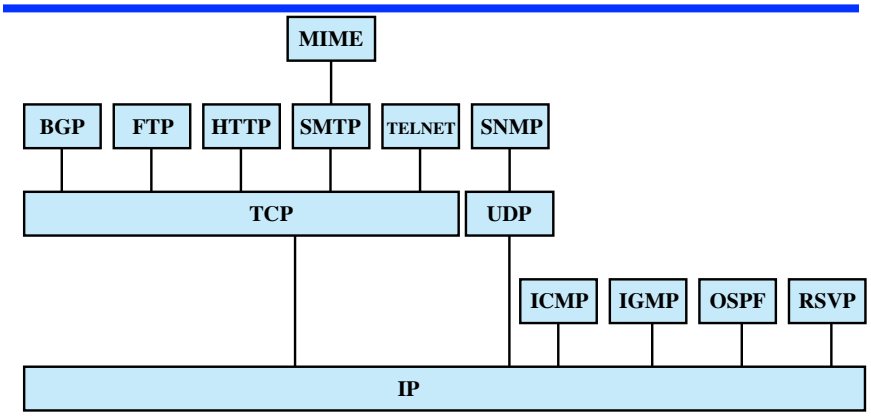
DS = Differentiated services field
ECN = Explicit congestion notification field

Note: The 8-bit DS/ECN fields were formerly known as the Type of Service field in the IPv4 header and the Traffic Class field in the IPv6 header.

TCP/IP Applications

- have a number of standard TCP/IP applications such as
  - —Simple Mail Transfer Protocol (SMTP)
  - —File Transfer Protocol (FTP)
  - —Telnet

Some TCP/IP Protocols

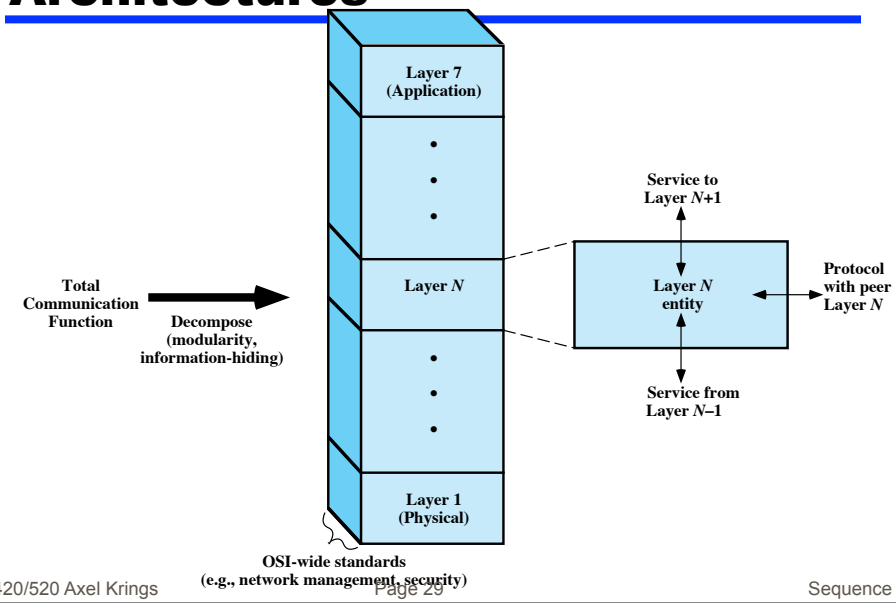


BGP = Border Gateway Protocol
FTP = File Transfer Protocol
HTTP = Hypertext Transfer Protocol
ICMP = Internet Control Message Protocol
IGMP = Internet Group Management Protocol
IP = Internet Protocol
MIME = Multipurpose Internet Mail Extension
OSPF = Open Shortest Path First
RSVP = Resource ReSerVation Protocol
SMTP = Simple Mail Transfer Protocol
SNMP = Simple Network Management Protocol
TCP = Transmission Control Protocol
UDP = User Datagram Protocol

OSI

- Open Systems Interconnection
- developed by the International Organization for Standardization (ISO)
- has seven layers
- is a theoretical system delivered too late!
- TCP/IP is the de facto standard

Standardized Protocol Architectures



OSI Layers

Application

Provides access to the OSI environment for users and also provides distributed information services.

Presentation

Provides independence to the application processes from differences in data representation (syntax).

Session

Provides the control structure for communication between applications; establishes, manages, and terminates connections (sessions) between cooperating applications.

Transport

Provides reliable, transparent transfer of data between end points; provides end-to-end error recovery and flow control.

Network

Provides upper layers with independence from the data transmission and switching technologies used to connect systems; responsible for establishing, maintaining, and terminating connections.

Data Link

Provides for the reliable transfer of information across the physical link; sends blocks (frames) with the necessary synchronization, error control, and flow control.

Physical

Concerned with transmission of unstructured bit stream over physical medium; deals with the mechanical, electrical, functional, and procedural characteristics to access the physical medium.

OSI Layers (1)

- Physical
  - —Physical interface between devices
    - Mechanical
    - Electrical
    - Functional
    - Procedural
- Data Link
  - —Means of activating, maintaining and deactivating a reliable link
  - —Error detection and control
  - —Higher layers may assume error free transmission

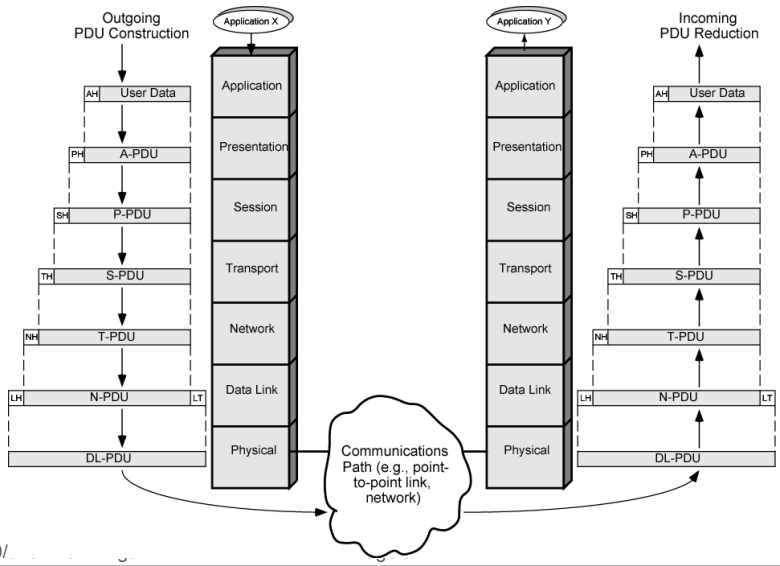
OSI Layers (2)

- Network
  - — Transport of information
  - — Higher layers do not need to know about underlying technology
  - — Not needed on direct links
- Transport
  - — Exchange of data between end systems
  - — Error free
  - — In sequence
  - — No losses
  - — No duplicates
  - — Quality of service

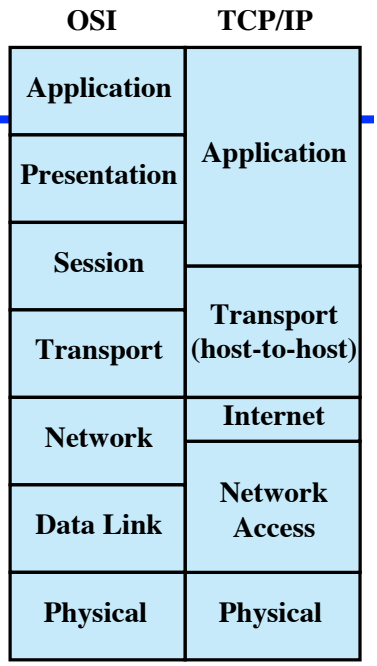
OSI Layers (3)

- Session
  - —Control of dialogues between applications
  - —Dialogue discipline
  - —Grouping
  - —Recovery
- Presentation
  - —Data formats and coding
  - —Data compression
  - —Encryption
- Application
  - —Means for applications to access OSI environment

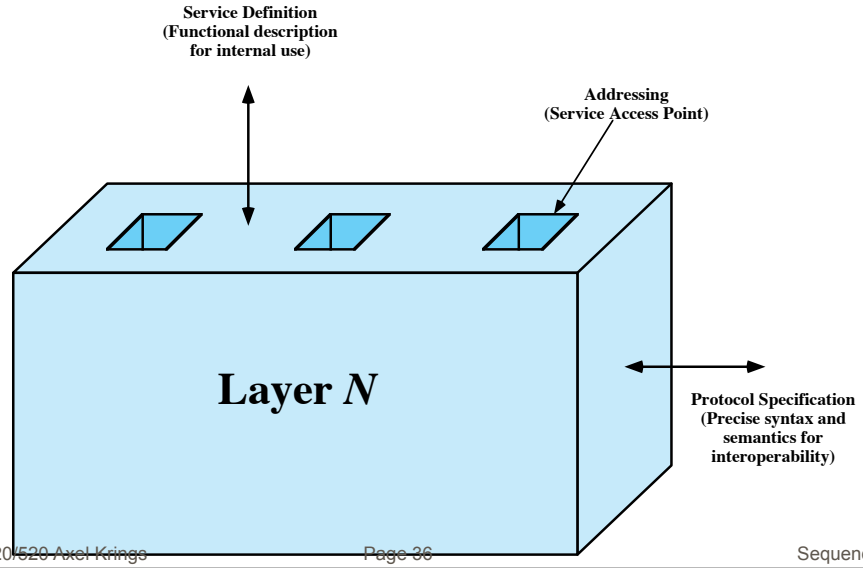
The OSI Environment



OSI vs TCP/IP

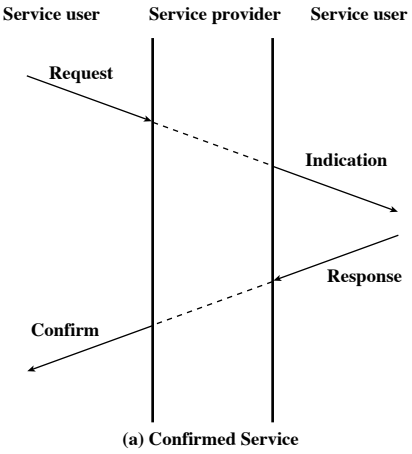


Layer Specific Standards



Service Primitives and Parameters

- define services between adjacent layers using:
- primitives to specify function performed
- parameters to pass data and control info



Primitive Types

REQUEST	A primitive issued by a service user to invoke some service and to pass the parameters needed to specify fully the requested service
INDICATION	A primitive issued by a service provider either to 1. indicate that a procedure has been invoked by the peer service user on the connection and to provide the associated parameters, or 2. notify the service user of a provider-initiated action
RESPONSE	A primitive issued by a service user to acknowledge or complete some procedure previously invoked by an indication to that user
CONFIRM	A primitive issued by a service provider to acknowledge or complete some procedure previously invoked by a request by the service user

Traditional vs Multimedia Applications

- traditionally Internet dominated by info retrieval applications
  - —typically using text and image transfer
  - —eg. email, file transfer, web
- see increasing growth in multimedia applications
  - —involving massive amounts of data
  - —such as streaming audio and video

Elastic and Inelastic Traffic

- elastic traffic
  - —can adjust to delay & throughput changes over a wide range
  - —eg. traditional “data” style TCP/IP traffic
  - —some applications more sensitive though
- inelastic traffic
  - —does not adapt to such changes
  - —eg. “real-time” voice & video traffic
  - —need minimum requirements on net arch
